

L07: Cryptography

- Cryptography is the study of methods for sending and receiving secret messages through insecure channels
- Outline:
 - **Private Key Cryptography**
 - Key Exchange
 - Public Key Cryptography and RSA
- Reading: Rosen 4.5, 4.6

Private Key Cryptography

- In private key cryptography, the sender (Alice) and the receiver (Bob) first agree on a common secret key in advance

Caesar Cipher (Shift Cypher)

- Encryption
 - The secret key k is a number from \mathbf{Z}_{26}
 - Replace each letter by an integer from \mathbf{Z}_{26}
 - The encryption function is $f(p) = (p + k) \bmod 26$. It replaces each integer p by $f(p)$.
 - Replace each integer by the corresponding letter
- Decryption
 - Just replace $f(p)$ with $f^{-1}(p) = (p - k) \bmod 26$ in the procedure above.

Caesar Cipher: Example

- **Example**

Encrypt the message “MEET YOU IN THE PARK” using $k = 3$

- **Solution**

- Replace letters by numbers:

12 4 4 19 24 14 20 8 13 19 7 4 15 0 17 10.

- Replace each of these numbers p by $f(p)$:

15 7 7 22 1 17 23 11 16 22 10 7 18 3 20 13.

- Translating the numbers back to letters
“PHHW BRX LQ WKH SDUN.”

Affine Ciphers

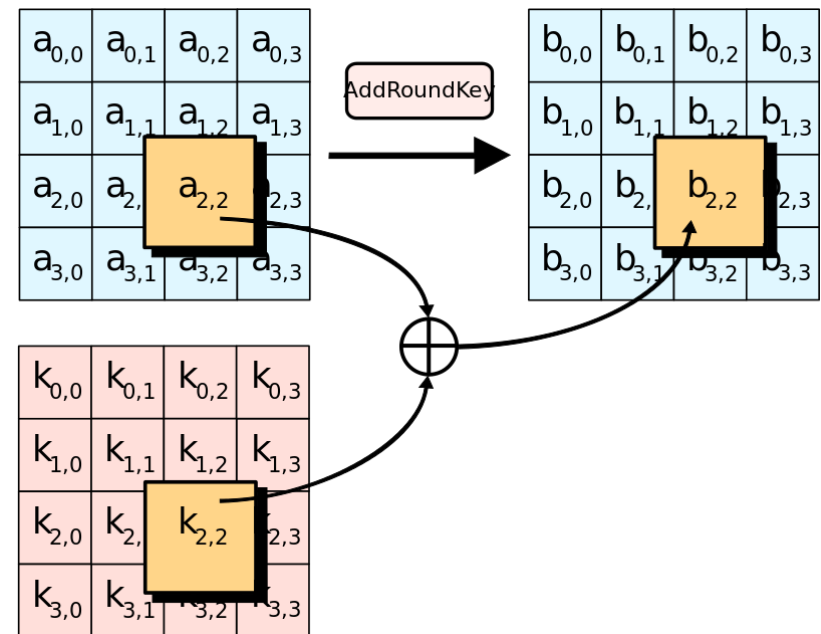

- The shift cipher is easy to break:
 - Just try all 26 possible keys!
- Affine ciphers make it (a little bit) safer by using both additions and multiplications
- Use the function $f(p) = (ap + b) \bmod 26$
 - The (a, b) pair is the secret key
 - Now there are $26^2 = 676$ possible secret keys
- However, suppose $a = 13, b = 1$
 - $f(1) = f(3) = 14$
 - If we receive a 14, which number does it decrypt to?
- How to fix?
 - Choose a such that $\gcd(a, 26) = 1$, e.g., $a = 7$
 - Then $ax + b \equiv y \pmod{p}$ has a unique solution

Block Ciphers

- Each character is a number between 0 and 255
 - A byte = 8 bits
- Partition the message into blocks of k characters
 - Treat each block as a big number of $8k$ bits
 - Use arithmetic modulo 2^{8k}
- Example
 - Choose $k = 10$
 - Encryption: $f(x) = ax + b \bmod 2^{80}$
 - Decryption: $f^{-1}(y) = a^{-1}(y - b) \bmod 2^{80}$
 - Now there are $\frac{2^{80}}{2} \times 2^{80} = 2^{159}$ different keys
- There are libraries on arbitrary-precision arithmetic

Advanced Encryption Standard (AES)

- Used in Transport Layer Security (TLS)
 - Previously known as Secure Sockets Layer (SSL)
 - Provides security for https, email, etc.
- A block cipher
 - Block size 128 bits
 - Key lengths: 128, 192, 256 bits
- Complicated operations that make it very difficult to break

Outline

- Private Key Cryptography
- **Key Exchange**
- Public Key Cryptography and RSA

Problems with private-key cryptography

- How to send the secret key?
 - Keys had to be transmitted in physical form in World War II
- How to distribute different keys to different customers?

New Security Device

The Key Exchange Puzzle

- Alice wants to send a valuable item to Bob, but the postman cannot be trusted
 - Alice can put an (unbreakable) lock on the box, but Bob cannot open it without the key
- Solution
 - Alice puts her lock on the box, and send it to Bob.
 - Bob, after receiving the box, puts his lock on the box as well, and returns to Alice.
 - Alice, after receiving the box, takes off her lock, and sends it back to Bob.
 - Bob takes off his lock and opens the box.

Modular Exponentiation

- How to compute

$$a^n \bmod m$$

efficiently for large n ?

- Repeated squaring method

- Compute

$$a^2 \bmod m$$

$$a^{2^2} \bmod m = a^4 \bmod m = (a^2 \bmod m)^2 \bmod m$$

$$a^{2^3} \bmod m = a^8 \bmod m = (a^4 \bmod m)^2 \bmod m$$

...

- Write n in binary $n = (b_k \dots b_1 b_0)_2$

- $a^n \equiv a^{b_0 \cdot 1} \cdot a^{b_1 \cdot 2} \cdot a^{b_2 \cdot 2^2} \dots \pmod{m}$

- Example: $n = 50 = (110010)_2$

- $a^{50} \equiv a^{2^1} a^{2^4} a^{2^5} \pmod{m}$

A Hard Problem: Discrete Logarithm

- “Locks” in cryptography correspond to problems that are believed to be computationally difficult
- Yes, if you can solve these problems, you can break current crypto systems
- Discrete logarithm is one such problem
 - Opposite of modular exponentiation
 - Given a prime p (potentially very large) and $r, a \in \mathbf{Z}_p$, find $x \in \mathbf{Z}_p$ such that

$$r^x \equiv a$$

- In 2015, it was reported that for 512-bit primes, the problem can be solved with a few thousands of CPUs in a week
 - Estimated cost to break 1024 bits: US\$100 million.

Diffie-Hellman Key Exchange

- Fix p and a
 - E.g., hardcoded in the TLS library
- The protocol
 - 1) Alice chooses a secret integer k_1 and sends $a^{k_1} \bmod p$ to Bob.
Secure to **eavesdropping**: Even this value is known to attackers, they cannot compute k_1
 - 2) Bob chooses a secret integer k_2 and sends $a^{k_2} \bmod p$ to Alice.
 - 3) Alice computes $(a^{k_2})^{k_1} \bmod p$.
 - 4) Bob computes $(a^{k_1})^{k_2} \bmod p$.
- The shared key is
$$(a^{k_1})^{k_2} \bmod p = (a^{k_2})^{k_1} \bmod p$$

Man-in-the-middle Attack

- If attacker intercepts all traffic between two parties
- Diffie-Hellman protocol can be compromised
- Attacker
 - communicates with Alice pretending as Bob
 - communicates with Bob pretending as Alice

Outline

- Private Key Cryptography
- Key Exchange
- **Public Key Cryptography and RSA**

Public Key Cryptography

- All previous ciphers need a common private key
- Encryption and decryption are symmetric
- The key has to be
 - communicated physically in private
 - using the DH protocol (secure to eavesdropping but not man-in-the-middle)
- Public key cryptography
 - Encryption and decryption are asymmetric
 - Everyone has
 - a public key: shared with everyone else
 - a private key: kept in private

The RSA Cryptosystem

Ronald Rivest
(Born 1948)

Adi Shamir
(Born 1952)

Leonard
Adelman
(Born 1945)

Clifford Cocks
(Born 1950)

- RSA was introduced in 1976 by RSA.
- In fact, Clifford Cocks, working secretly for the UK government, discovered it 3 years earlier.
 - Made known to public in late 1990s.

Another Difficult Problem: Factoring

- Let $n = pq$, where p and q are large primes (e.g. 1024 bits or longer)
- The factoring problem: Given n , find p and q
- On the other hand, it is known how to find large primes efficiently
- Public key in RSA: n and e , such that e is relatively prime to $(p - 1)(q - 1)$
- Private key in RSA: p and q
- Everyone uses a different set of keys

```

RSA Encryption

- Let $x < n$ be the message to be encrypted
- Alice encrypts it as

$$C = x^e \bmod n$$

- (n, e) is Bob's public key
 - Sends C to Bob
 - C may be eavesdropped
- Security
 - Exponentiation can be computed efficiently
 - Proportional to the length of the key
 - Computing x from (n, e) is believed to be difficult
 - Similar to discrete logarithm

RSA Decryption

- Bob receives C
- Bob decrypts x from C using his private key (p, q)
 - Find d , the inverse of e modulo $(p - 1)(q - 1)$, i.e.,
$$de \equiv 1 \pmod{(p - 1)(q - 1)}$$
 - Compute
$$C^d \pmod{n}$$
- Will show later that $C^d \equiv (x^e)^d \equiv x^{de} \equiv x \pmod{n}$
- Security:
 - It's hard to find d without knowing (p, q)

RSA in Use

- Sending secrete messages
 - Divide message into blocks such that each block is a number $< n$
 - Alice encodes her message using Bob's public key
 - Bob decodes the message using his private key
- Digital signatures (authentication)
 - Alice encodes her message using her private key
 - Computes $C = x^d \bmod n$
 - Bob (or anyone else) decodes the message using Alice's public key
 - Computes $C^e \bmod n = x^{de} \bmod n = x$
 - He will know the message indeed came from Alice

RSA in Use

- How to prevent man-in-the-middle attacks?
- How to make sure that Alice's public key indeed belongs Alice?
- Certificate authority (CA)
 - A small number of trusted third parties:
Comodo, Symantex, GoDaddy, GlobalSign, ...
- How to make sure that a CA's public key indeed belongs to that CA?
- Built into Internet browsers
- How can I trust my browser and the CAs?
- Well, you have to ...

RSA: Correctness

- **Proof plan**

We want to show

$$C^d = x^{de} \equiv x \pmod{n}.$$

Step 1: Show that

$$x^{de} \equiv x \pmod{p}$$

$$x^{de} \equiv x \pmod{q}$$

Step 2: Show that

$$x^{de} \equiv x \pmod{pq}$$

Fermat's Little Theorem

Pierre de Fermat
(1601-1665)

- **Theorem**

If p is prime and a is an integer not divisible by p , then

$$a^{p-1} \equiv 1 \pmod{p}$$

- Proof omitted
- Useful in computing the remainders of large powers

- **Example:**

Find $7^{222} \pmod{11}$.

By the theorem, we know that $7^{10} \equiv 1 \pmod{11}$, and so $(7^{10})^k \equiv 1 \pmod{11}$, for any positive integer k .

Therefore,

$$7^{222} = 7^{22 \cdot 10 + 2} = (7^{10})^{22} \cdot 7^2 \equiv 1^{22} \cdot 49 \equiv 5 \pmod{11}$$

RSA Correctness Step 1

- **Proof**

We know d is the inverse of e modulo $(p-1)(q-1)$, so
$$de = 1 + k(p-1)(q-1).$$

It follows that

$$\begin{aligned} C^d &\equiv (x^e)^d \pmod{p} \\ &\equiv x^{de} \pmod{p} \\ &\equiv x^{1+k(p-1)(q-1)} \pmod{p} \end{aligned}$$

Case 1: $x^{k(q-1)}$ is not a multiple of p .

Applying Fermat's Little Theorem with $a = x^{k(q-1)}$:

$$x^{k(p-1)(q-1)} \equiv 1 \pmod{p},$$

so

$$x^{1+k(p-1)(q-1)} \equiv x \pmod{p},$$

RSA Correctness Step 1 (cnt'd)

- Case 2: $x^{k(q-1)}$ is a multiple of p .

Then

$$x^{k(p-1)(q-1)} \equiv 0 \pmod{p}$$

$$x^{1+k(p-1)(q-1)} \equiv 0 \pmod{p}$$

On the other hand, since $x^{k(q-1)}$ is a multiple of p and p is a prime, then x must be a multiple of p . So

$$x \equiv 0 \pmod{p}$$

Thus in this case, we have

$$x^{1+k(p-1)(q-1)} \equiv x \equiv 0 \pmod{p}.$$

- The proof for $x^{de} \equiv x \pmod{q}$ is symmetric.

RSA Correctness Step 2

- A simple property of prime numbers
 - If p and q are both primes and $p \mid z, q \mid z$, then $pq \mid z$
- Proof of Step 2:

- We already have

$$x^{de} \equiv x \pmod{p}$$

$$x^{de} \equiv x \pmod{q}$$

- So,

$$p \mid (x^{de} - x)$$

$$q \mid (x^{de} - x)$$

- Therefore,

$$pq \mid (x^{de} - x)$$

$$x^{de} \equiv x \pmod{pq}$$
